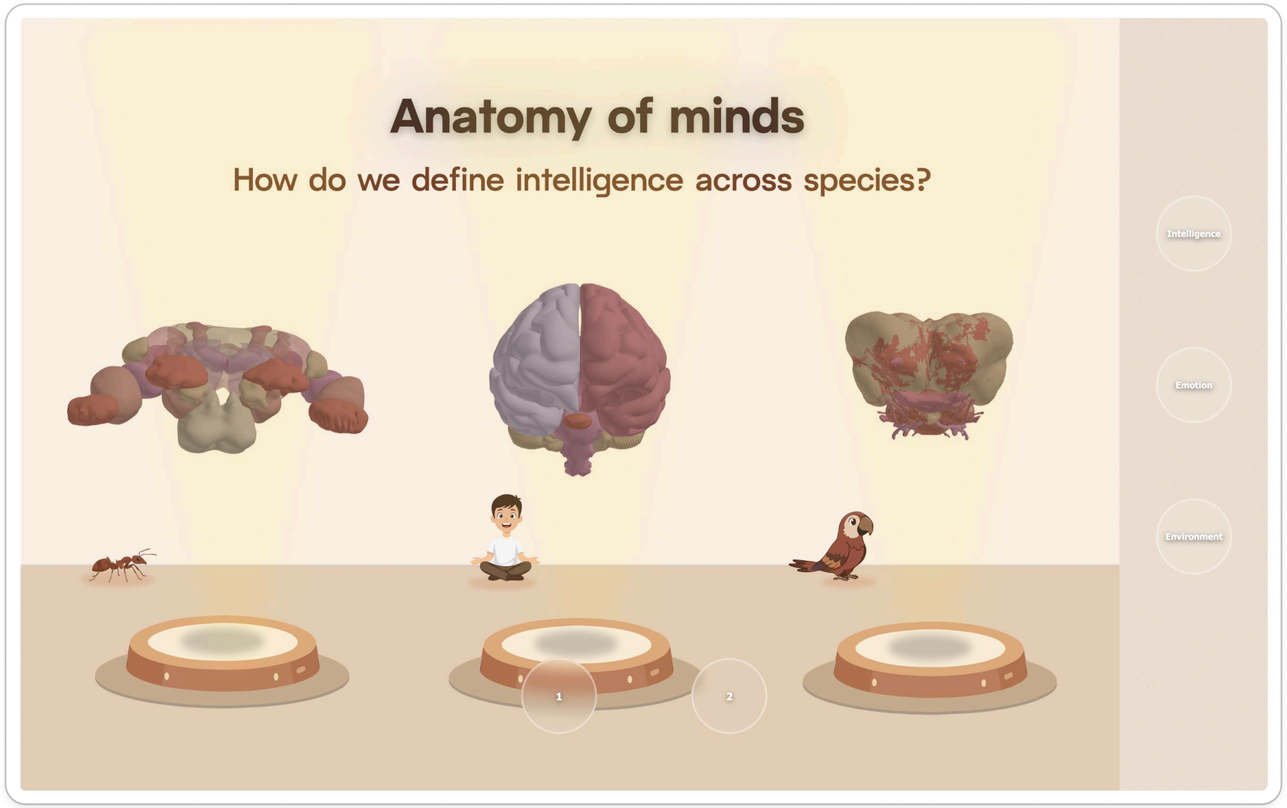
# Design Concept

After clearly defining how we wanted the interaction to work and how we would communicate the information, we established the final development of the project. We decided to create an interactive platform that would display information about the emotions, intelligence, and environment of different species. This platform would be controlled through tangible species figures, which, when placed on sensors, would identify the figure and display the corresponding information.


Additionally, a 3D model of the corresponding species brain would be displayed, which could be rotated by turning the tangible object. Likewise, specific areas of the brain would be highlighted depending on the information being presented—for example, when displaying emotional data, the brain regions associated with the analyzed emotion would be illuminated.
