Concept Development

Because of the exhibition's broad audience—from young children to adults—our team designed the physical interaction as a board game-like experience. We incorporated 3D-printed figures (representing species like elephants, birds, ants, and humans) that users place on designated points.

This approach grants users freedom of choice, encouraging curious exploration to discover what happens at each point. It fosters intuitive, self-directed learning without overwhelming instructions.

Since we wanted to display dynamic 3D brain models with information that adapts to user choices, our team opted for tabletop projection.

This projects interactive brain visualizations and details directly onto the board surface, changing in real-time based on the figure's position.
